TITLE OF THE INVENTION

DOOR CONDITION SENSOR FOR SAFES AND SECURED AREAS

BACKGROUND OF THE INVENTION

Electronic combination locking systems for controlling entry to safes are now widely used in vault doors and especially in small to medium size safes. Such digital combination locking systems have included, for example, individual access codes for authorized personnel to use for opening safes. Automatic recordation of entry times associated with user access codes have also been used. Ability to retrieve records of such events at a later date and automatic alarms have also been used with locking systems for safes. Examples of the art in electronically controlled locking systems can be found in U.S. Patent Nos. 4,904,984 and 5,617,082.

However, in order to provided further security to such electronically controlled locking systems against misuse by authorized users and against burglars, continual improvement in electronically controlled locking systems is needed.

This invention provides additional security by enabling continuous monitoring of the condition of safe and vault doors or other entry doors to a secured areas without the use of a camera or closed circuit television. It is also an object of this invention to provide a relatively inexpensive and

1 reliable door monitoring means for use with electronically
2 controlled locks.

3 BRIEF SUMMARY OF THE INVENTION

4 The door condition sensor of this invention is for use
5 with electronic access control devices include electronic
6 combination locks, for use with safes, and especially
7 electronic locking systems having memory means for entry to
8 secure areas. Such locking systems including locking
9 apparatus using local area network communication systems to
10 control access to safes having a plurality of doors such as an
11 outer door with a lower level of security and an inner door
12 with a higher level of security.

13 In particular, with reference to FIG. 1, a schematic
14 diagram of an electronic locking system of this invention is
15 shown having power supply means 150 with power AC-adapter
16 connector 151 electrically linked by cables 101, 102 and 103
17 to outer electronic lock/memory means 200 and inner electronic
18 lock/memory means 210. Means 200 and 210 are electrically
19 linked to controller/memory means 160. Controller/memory
20 means 160 has a keypad 161 for inputting user information and
21 display screen 162 for viewing output information such as door
22 condition status information. Means 200 and 210 have door
23 handles 201 and 211, respectively, for physically unlocking
24 and locking the locks when proper input codes have been
25 entered to the system. Door handle 201 extends through door

1 22, for example an outer door, with the remainder of means 200
2 secured to the inside of door 22. Door handle 211 extends
3 through door 212, for example an inner door, with the
4 remainder of means 210 secured to the inside of door 212.
5 Power supply means 150 has printer port 152 for connecting to
6 a printer or other device for retrieval of audit data stored
7 in the memory of the system. Power AC-adaptor connector 151
8 is connected to power supply means 150 by cable 104.

9 This invention features a door condition sensor or
10 sensors 20 that senses the condition of a door or doors in or
11 to the safe or secure area. In this embodiment, one sensor
12 monitors the condition of outer door 22 and the other sensor
13 monitors the condition of inner door 212. Each door condition
14 sensor 20 is mounted on the interior surface of the safe door
15 the condition of which is to be monitored. Each sensor 20 is
16 electrically linked by cables 100 to a particular lock for the
17 monitored door as shown schematically in FIG. 1. The system's
18 memory continually monitors the condition of the safe door and
19 creates an auditable record of that condition. Means 160 is
20 secured to the outside of the safe at a convenient location.
21 Means 150, also secured to the safe, can be located at any
22 convenient location inside or outside the safe. FIGS. 2-15
23 describe the details of door condition sensor 20 and the
24 relationship between sensor 20 and the locking system of
25 FIG. 1.

1 BRIEF DESCRIPTION OF THE DRAWINGS

2 FIG. 1 is a schematic of the door condition sensors of
3 this invention and associated electronic locking components
4 used therewith.

5 FIG. 2 top view of the door condition sensor and
6 electrical components as mounted on a safe door.

7 FIG. 3 is an exploded view of the door condition sensor
8 of FIG. 2 as seen from the opposite side thereof.

9 FIG. 4 is a partially assembled view of the door
10 condition sensor of FIG. 3 in a retracted state.

11 FIG. 5 is a partially assembled view of the door
12 condition sensor of FIG. 3 in a fully extended state.

13 FIG. 6 a cross-sectional view of the door condition
14 sensor in a fully extended state from the opposite side of
15 that shown in FIG. 5.

16 FIG. 7 is a top view of the sensor housing of the door
17 condition sensor of FIG. 6.

18 FIG. 8 is cross-sectional view of the housing cover of
19 the door condition sensor of FIG. 6 from the opposite side of
20 that shown in FIG. 6.

21 FIG. 9 is a detail of encircled Section 9 of FIG. 3 as
22 seen from the opposite side thereof.

23 FIG. 10 is a front view of the rotatable driver of the
24 door condition sensor of FIG. 6.

25 FIG. 11 is a top view of the rotatable driver of FIG. 10.

1 FIG. 12 is a side view of the analog signal generator
2 means of the door condition sensor as seen from the opposite
3 side of FIG. 6.

4 FIG. 13 is the electrical circuit of the analog signal
5 generator means of FIG. 12.

6 FIG. 14 is a flow chart for setting the initial operating
7 parameters for the door condition sensor.

8 FIG. 15 is a flow chart for monitoring the door condition
9 sensor.

10 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

11 The use of the terms "up", "upstanding", "down" and
12 "downstanding" as used herein refers only to the orientation
13 of elements as they appear in the FIGS. 3-6 and 8 and not to
14 actual orientation of such elements when mounted on a vertical
15 door of a safe or vault. The actual orientation of such
16 elements when incorporated in a safe or vault is preferably as
17 shown in FIG. 2. FIGS. 3-6 and 8 are rotated 90° to FIG. 2.

18 FIG. 2 shows a door condition sensor 20 of this invention
19 in both the door closed position and the door opened position,
20 with the latter shown in phantom. In particular, door
21 condition sensor 20 is shown installed on a chamber 21, for
22 example a safe or vault, having a door 22 and a door frame 23
23 therefor. Door condition sensor 20 is mounted to the inside
24 surface 24 of door 22. As opposed to FIG. 1, FIGS. 2-15 are
25 illustrative of a single electronically controlled lock

1 systems. However, system with a plurality of doors having
2 electronically controlled locks, as shown in FIG. 1, will
3 function in a similar manner.

4 With reference to FIGS. 2-12, door condition sensor 20
5 comprises a sensor housing 30, door frame engageable means 50,
6 rotatable driver means 70, analog signal generator means 80,
7 biasing means 110, and a housing cover 120.

8 The base portion of sensor housing 30 has an opening 31
9 for insertion of fastener 25 for securing housing 30 to the
10 inside surface 24 of door 22. Housing 30 has an internal
11 channel 32 for insertion of biasing means, which in this
12 embodiment, is a coil extension spring 110.

13 Housing 30 also has an upstanding hollowed internally
14 threaded post 33 having axis 34. An upstanding potentiometer
15 bracket 35 having axis 37 and several small traverse openings
16 36, is provided for receiving small conjunctively-shaped
17 snap-in mounting prongs 81 of analog signal generator means
18 80. Analog signal generator means 80 is mounted in housing 30
19 by first inserting opening 82 down over post 33 and then
20 inserting snap-in-place mounting prongs 81 in openings 36
21 thereby completing the mounting of analog signal generator
22 means 80 in housing 30 with the base of circuit board 87
23 resting on supports 45 and 46.

24 Door frame engageable means 50 has a ramp-shaped leading
25 surface 51 for striking and abutting the jamb of door frame 23

1 as door 22 is closed, so that frame engageable means 50 is
2 easily displaced into the sensor housing 30.

3 Rotatable driver means 70 is a segmented gear having
4 outwardly extending gear teeth 71 and shaft 72. When
5 assembled in housing 30, the axis of brackets 35 and 38 of
6 shaft 72 coincides with the axis 37 of housing 30. One end 73
7 of shaft 72 is rotatably supported by upstanding shaft support
8 bracket 38 of housing 30. Support bracket 38 has a
9 hemispherical central cup depression 39 and flat uppermost
10 support surface 40. When sensor 20 is assembled the axes of
11 cup depression 39 and shaft 72 coincide with the axis 37 of
12 housing.

13 The opposite end 74 of shaft 72 has a cross-sectional
14 shape designed to fit into a complementary shaped axial
15 opening 83 in rotatable part 84 of analog signal generator
16 means 80. In the embodiment shown in the figures, the cross-
17 sectional shape of opening 83 is rectangular. In this
18 embodiment, hemispherically shaped end 73 of shaft 72 is
19 rotatably supported by hemispherically shaped cup depression
20 39 in support bracket 38 and rectangular opening 83 in
21 rotatable part 84 of potentiometer 85. The shape of opening
22 83 need not be rectangular but must be such that as shaft
23 turns part 84 turns.

24 Frame engageable means 50 has a linear set of gear teeth
25 52 downwardly extending for engaging complementary outwardly
26 extending gear teeth 71 of the rotatable driver means 80 as

1 best seen in FIG. 6. Therefore, as frame engageable means 50
2 slides into and out of housing 30, gear teeth 52 of means 50
3 engage gear teeth 71 of means 70 and drive rotatable driver
4 means 70 which in turn rotates rotatable part 84 of
5 potentiometer 85 of analog signal generator means 80.

6 To maintain ramp-shaped leading surface 51 outwardly
7 extended and against door frame 23, one end of coil extension
8 spring 110 is inserted into internal channel 32 of housing 30.
9 The other end of spring 110 is inserted over elongated prong
10 53 of frame engageable means 50. When sensor 20 is assembled,
11 spring 110 is confined entirely to channel 32 and prong 53,
12 thereby maintaining spring 110 in a straight line and
13 preventing it from becoming dislodged. Coil extension spring
14 110 is designed to be strong enough to extend frame engageable
15 means 50 outward from housing 30 sufficiently to maintain
16 ramp-shaped leading surface 51 against the jamb of door frame
17 23 when door 22 is closed or nearly closed but not strong
18 enough to interfere with, or prevent, the closing of door 22.

19 A lower edge 54 of frame engageable means 50 rests on the
20 flat uppermost surface 40 of support bracket 38 thereby
21 preventing means 50 from tilting downwardly into housing 30.

22 Housing cover 120 has a downstanding alignment tab 121
23 extending from the lower edge 122 of one sidewall that is
24 received in upstanding alignment recess 41 of housing 30.
25 Insertion of alignment tab 121 into recess 41 registers cover
26 120 in exact longitudinal alignment with housing 30.

1 Sensor housing 30 has parallel upstanding sidewalls 42
2 having recessed upper edges 43 for registry with
3 conjunctively-recessed lower edges 122 of parallel
4 downstanding sidewalls 123 of housing cover 120 thereby
5 maintaining cover 120 in exact alignment transversely with
6 housing 30.

7 To limit the travel of frame engageable means 50 relative
8 to housing 30, frame engageable means 50 has a linear stop
9 slot 55 approximately equal in length to the total extension
10 of means 50 from housing 30. Slot 55 is a three-sided
11 rectangular shaped notch or opening in this embodiment.
12 Housing cover 120 has a downstanding internal stop 124 that is
13 positioned within the stop slot 55 when the cover 120 is
14 fastened to housing 30. Slot 55 and stop 124 confine the
15 linear movement of the frame engageable means 50 approximately
16 between closed-door position and an opened door or
17 out-of-set-point position, that is away from door frame or
18 door jamb 23 as shown in the phantom-lined projection of
19 opened door 22 of FIG. 2 and FIG. 6.

20 Housing cover 120 has an inside flat top surface 125 that
21 when sensor 20 is assembled has a very small clearance between
22 outer flat top surface 56 of frame engageable means 50 and
23 surface 125 thereby further preventing means 50 from tilting
24 within the assembled sensor 20.

25 Housing cover 120 also has an opening 126 alignable with
26 internally threaded post 33 through which fastener 127 is

1 screwed to secure cover 120 to housing 30, thereby
2 simultaneously securing and entirely confining all components
3 of door condition sensor 20 in the assembled housing 30 and
4 cover 120 except for the extended part of frame engageable
5 means 50.

6 Lower internal cable compressive buttress 44 in housing
7 30 in conjunction with upper internal cable compressive
8 buttress 128 in housing cover 120 squeeze and thereby anchor
9 electrical cable 100 in the assembled housing 30 and cover
10 120. A male telephone-type jack located at one distal end of
11 cable 100 is snap connected into female telephone-type jack 86
12 of analog signal generator means 80. Cable 100 provides
13 constant input signal or voltage to and analog signal output
14 from, analog signal generator means 80.

15 Female jack 86 is electrically connected to base circuit
16 board 87 of analog signal generator means 80, which is
17 electrically connected to potentiometer 85. As shown in
18 FIG. 12, potentiometer 85 has an upstanding stationary part 88
19 and a complementary rotatable part 84 that is rotatably
20 mounted in stationary part 88. When assembled the axis of
21 parts 88 and 84 coincides with axis 37 of upstanding
22 potentiometer bracket 35 and cup recess 39 of support bracket
23 38 of housing 30.

24 To augment axial alignment of shaft 72 of rotatable
25 driver means 80 to rotatable part 84 of potentiometer 85, part
26 84 has a small width and small height annular boss 89 into

1 which a portion of enlarged central cylindrical axial portion
2 76 of shaft 72 fits. The outer cylindrical surface of annular
3 boss 89 fits within central circular opening 47 of
4 potentiometer bracket 35. The small width of annular boss 89
5 separates axial portion 76 from opening 47. Because the width
6 of boss 89 is small, for example about 0.016 inches, boss 89
7 is merely shown as a circle in FIG. 12. The small height of
8 annular boss 89 provides no detrimental resistance to the
9 rotation of axial portion 76 of rotatable driver means 70 in
10 central circular opening 47 in potentiometer bracket 35
11 thereby enabling potentiometer 85 to function with no
12 detrimental mechanical resistance as a result of the rotation
13 of rotatable driver means 70 and rotatable part 84.

14 Circuit board 87 also contains a light 90, for example a
15 light emitting diode, that is lit when power is provided to
16 analog signal generator means 80. A small beam of light,
17 emitted from light 90 and shone through small aperture 129
18 immediately above downstanding annular member 130 in cover
19 120, indicates that the power is on to sensor 20. Light 90
20 serves as a diagnostic indicator for troubleshooting. Annular
21 member 130 abuts light 90 on base circuit board 87 thereby
22 also holding board 87 down against circuit board supports 45
23 and 46 and channeling the light to aperture 129. Upper
24 buttress 128 and annular member 130 depend from a section 131
25 of cover 120. The height of section 131 provides little
26 clearance between it and the top of female jack 86 thereby

1 further preventing any detrimental movement of jack 86 within
2 the door condition sensor.

3 Referring to FIG. 2, electrical power input is provided
4 to electronic lock/memory means 200 from power supply means
5 150 by cables 103 and 101. Output signal from means 200 is
6 transmitted to analog signal generator means 80 by cable 100.
7 Analog signal from means 80 is transmitted back to means 200
8 by cable 100. Digital signal from means 200 is transmitted to
9 and from controller/memory means 160 by cable 101.
10 Lock/memory means 200 is mounted on the inside surface 24 of
11 door 22. Power supply means 150, also shown mounted on the
12 inside surface 24 of door 22, can be positioned on the outside
13 of the safe if desired or more convenient. Controller/memory
14 means 160 is mounted on the outside surface of door 22. Means
15 160 and 200 provide conversion means for converting the analog
16 signal from analog signal generator means 80 to corresponding
17 digital signal, and digital signal to corresponding
18 displacement in inches of leading surface 51.

19 Means 160 also comprises a data entry means, namely a
20 keypad 161, and display screen 162, for entering information
21 into the locking system for gaining entry into the safe, and
22 for viewing entered and monitored data associated with door
23 condition sensor 20. Data entry includes operating
24 parameters, which include in part a preset set point, a
25 tolerance and a preset set point range.

1 FIG. 13 shows a circuit diagram for analog signal
2 generator means 80 in which electrical elements corresponding
3 to mechanical elements in FIGS. 2-12 have been assigned the
4 same element numbers. In particular the circuit comprises
5 female telephone jack 86 that is shown as an electrical
6 connector. The circuit also comprises resistors 91 and 92,
7 capacitor 93, ground 94, and potentiometer 85 with rotatable
8 part 84 represented electrically by the variable resistor.
9 Terminals 86a and 86b provide signal input or voltage to means
10 80 and terminal 86c and 86d provide analog signal output.

11 Door condition sensor 20 can be economically produced by
12 plastic molding of the following individual parts, sensor
13 housing 30, frame engageable means 50, rotatable driver 70 and
14 housing cover 120. Furthermore, analog signal generator means
15 80 can also be inexpensively produced.

16 After the safe is installed in its permanent location,
17 preferably with anchor bolts embedded in high strength cement
18 or concrete, and the basic lock parameters codes entered in
19 the safe's memory through means 160, the owner then enters the
20 initial operating parameters for the door condition sensor 20
21 for a program such as that illustrated by flow chart of FIG.
22 14.

23 In particular the owner will log in by entering his or
24 her personal identity code through keypad 161, or other
25 identity input terminal, as represented in step 170. Using

1 the keypad the owner then navigates to the main menu as
2 represented in step 171.

3 With door 22 closed as represented by step 172,
4 ramp-shaped leading surface 51 of frame engageable means 50
5 will be in the closed-door position as shown in FIG. 2. The
6 owner then notes the exact extension or position of leading
7 surface 51 as shown on display screen 162 of means 160. The
8 program converts the analog signal corresponding to the
9 extension or position of ramp-shaped leading surface 51 to a
10 corresponding digital signal and then to corresponding inches
11 of extension.

12 The initial set up, in one embodiment of this invention,
13 proceeds as follows. If the full extension of ramp-shaped
14 leading surface 51 is $3/4$ inch, door condition sensor 20 is
15 mounted on door 22 so that the closed door position of
16 ramp-shaped leading surface 51 is about $3/8$ inch, i.e. about
17 half of the full extension. The owner then selects the noted
18 closed-door extension in inches through keypad 161 as the
19 preset set point as represented in step 173.

20 Thereafter, each time door 20 is closed the location of
21 ramp-shaped leading surface 51 is compared preset set point by
22 the system's memory. Ideally all future screen displays of
23 the closed-door position or extension will be exactly the same
24 as the preset set point. However, due to wear of mechanical
25 parts of the safe, future closed-door extensions may vary
26 slightly from the initially selected preset set point, for

1 example a few hundredths of an inch. Therefore, to provide
2 for such non-detrimental and acceptable variations in the
3 preset set point, a tolerance is selected using keypad 161 as
4 represented in step 174.

5 For example, the tolerance can be set to ± 0.030 inches.
6 The sum of the preset set point \pm the tolerance define a
7 preset set point range for the door condition sensor. The
8 preset set point range is also entered and stored in the
9 system's memory as represented by step 175. The preset set
10 point range is then used by the locking system to judge
11 whether or not door 22 is properly closed and whether there
12 has been a time sequence violation or a compromising activity.
13 The preset set point, the tolerance and the preset set point
14 range remains in the locking system's memory until changed.

15 After setting the operating parameters as described with
16 reference to FIG. 14, the locking system is provided with a
17 program associated with the extension activity of leading
18 surface 51 of frame engageable means 50, for constantly
19 monitoring the safe for time violations and unauthorized
20 activities.

21 In particular with reference to the program represented
22 by the flow chart of FIG. 15, when the locking system
23 indicates that the extension of leading surface 51 is within
24 its preset set point range and that door 22 is locked, the
25 safe is deemed idle and secure as represented in step 180.

1 To gain entry a duly authorized person must log in with
2 his or her personal identifier as represented in step 181. If
3 the log in identifier is accepted by the locking system, the
4 safe is ready for entry of the unlocking code. The user can
5 then enter the unlocking code and unlock the safe door as
6 represented by step 182.

7 Next the program asks if the safe door 22 has been opened
8 as represented by step 183. If after a predetermined allowed
9 unlocking time the safe has not been opened, the program
10 returns to the idle state as represented by step 180. In
11 FIG. 15 the conventional letters N and Y stand for no and yes.

12 If the safe door is opened within the predetermined
13 unlocking allowed time, the program recalls from memory a
14 previously stored allowed open period as represented by step
15 184. For example the allowed open period can be set for about
16 1.5 minutes for a safe used only to store money periodically
17 as it is received in a retail business. The allowed open
18 period will, of course, depend on the actual normal usage of
19 the safe.

20 In step 185, the program continually compares the time
21 lapse since the safe door is opened with the allowed open
22 period and asks if the allowed open period is up. If the
23 allowed open period is up before the safe door is closed, the
24 system activates an alarm as represented by step 186. The
25 program then stamps an audit record with the time the event
26 occurred as represented by step 188.

1 If the time has not lapsed, the program continuously asks
2 if the door has been closed as represented by step 187. If
3 the door has been closed and locked, the program returns to
4 step 180 and awaits for further instruction. If the door is
5 still open the program returns to step 184 for continued
6 monitoring of the open door count down time.

7 The program also continually monitors the safe to
8 determine if there is an attempted compromise as represented
9 by step 190. This is accomplished by the program continually
10 asking if leading surface 51 of door condition sensor 20 is
11 out of the preset set point range as represented by step 191.
12 If the door condition sensor and program indicate that leading
13 surface 51 is out of preset set point range that may indicate
14 that someone is testing the safe for ways to circumvent the
15 program, or that someone is prying on the door, or that the
16 door is partly but not completely closed, or for another
17 reason that may not be associated with normal activity of the
18 safe.

19 If the program indicates that the door condition sensor
20 is out of preset set point range the program activates an
21 alarm as represented by step 192. The program then stamps an
22 audit record with the time the event occurred as represented
23 by step 193. However, if the program indicates that the door
24 condition sensor is not out of preset set point range, the
25 program then reverts to the idle and secure state as
26 represented by step 180.

1 Thus, when a suspect activity occurs, the program stamps
2 the event thereby producing a retrievable record of such
3 events for subsequent evaluation by security personnel. The
4 audit trail can be used for aiding in the determination of
5 whether the tampering activity was by authorized personnel or
6 by an unauthorized person such as a burglar. By connecting a
7 printer to printer connector port 152 in power supply means
8 150, printed audit reports can be produced.

9 Therefore, the door condition sensor 20 and the locking
10 system of this invention provides both means for determining
11 (1) whether there has been any activity which violates
12 predetermined set time limits for the door 22 to be open, and
13 (2) whether there has been any activity that would suggest
14 that a compromising activity has occurred.

15 While the preferred embodiments of the present invention
16 have been described, various changes, adaptations and
17 modifications may be made thereto without departing from the
18 spirit of the invention and the scope of the appended claims.
19 The present disclosure and embodiments of this invention
20 described herein are for purposes of illustration and example
21 and modifications and improvements may be made thereto without
22 departing from the spirit of the invention or from the scope
23 of the claims. The claims, therefore, are to be accorded a
24 range of equivalents commensurate in scope with the advances
25 made over the art.
